

Five apps, one order-to-cash loop

Who opens which screen, in what order, and what the system records at each step.
Two store binaries (the Team app with four role modules, and the Retailer app)
plus the owner's web console, all on one API and one tenant-isolated database.

- Records the system writes

Needs a human decision

Exception / return path

Outside party (retailer, brand DMS)

System map: people, surfaces, one backend

A person is one login (phone). Each distributor they work with is a separate tenant; the role on that tenant decides which modules open. A shop can be linked to several distributors and sees one card per link.

The loop every rupee travels

One sales order is the primary record; the invoice is issued once at pack and never edited; money is a separate receipt allocated to bills. The same loop runs whether the order came from a rep, the shop's own app, WhatsApp, or a van sale.

FIG. 2 – ORDER TO CASH ACROSS THE FIVE APPS

FIXED RULE An issued GST invoice is never edited. A short delivery or return becomes a credit note at the original rate; a bill cancelled before dispatch keeps its number with state `cancelled`. Payment state is derived from receipts and allocations, never written on the invoice.

Salesperson: the beat day

Rahul covers Station Road on Mondays and Thursdays. Everything works with no signal; the phone uploads when it can. A rep employed by a brand (Pooja for Too Yumm) sees only that brand's items.

offline-first

PowerSync

Hindi / English

never sees cost or margin

FIG. 3 — FROM “AAJ KA BEAT” TO A CONFIRMED ORDER

Screens

- **Beat** · today's shops, pending-undelivered, outstanding.
- **Shop card** · last order, usual basket, days since visit, request bargain.
- **Order editor** · shared with the retailer app.
- **Performance** · target, achievement, computed incentive (no payroll).

What gets recorded

- `visits` with outcome and geo-tag.
- `sales_orders` + lines with `entered_qty / unit` and `applied_rules`.
- `bargain_requests`, auto-approved inside the rep's bound.
- `sync_ops` so a retried upload never double-posts.

Manager: stock in, orders out

Vikas runs the godown. Inbound is the “zero typing” promise: a manufacturer invoice enters stock by photo, with the blind gate count as the only typed number. Outbound turns confirmed orders into packed cartons, legal invoices and a loaded van.

A4 print from the console

GRN never auto-commits

BRAND DMS Too Yumm mandates FieldAssist for billing. Those invoices are captured the same way as inbound bills and committed as `source = brand_dms_import`, so delivery, collection and outstanding stay complete without a second legal invoice. Day-end is a count: “DMS printed 23, we captured 23”.

Delivery crew: the trip

Ganesh drives, Raju collects. A vehicle is a stock location, so the crew inherits stock responsibility from check-out to check-in. Location is shared only while a trip is active and the phone says so in a persistent notification.

offline-first

trip-scoped GPS

van sales from vehicle stock

FIG. 6 – START TRIP TO SETTLEMENT

What the shop gets

- Invoice PDF and POD on WhatsApp at delivery.
- A receipt message the moment cash or UPI is taken.
- ETA from the trip, never the crew's live trace.

What the owner sees

- Live map from one position per vehicle.
- Cash in transit per trip; red settlements in the approvals queue.
- Raw GPS points expire after 90 days; stop coordinates and POD stay with the invoice.

Owner: decide on the phone, configure at the desk

Sunil approves from the phone between calls and sits at the console with the CA. The console is also where a new distributor is set up: catalog listing, costs, retailers, price lists, schemes, staff and beats.

only role that sees margin

GUARANTEE Purchase cost and margin live in a table only owner, manager and accountant roles can read. That is a database rule (row-level security) plus a test that runs on every change, not a screen setting.

Retailer: the shop's side of the ledger

Shree Ganesh Kirana buys from Tarsun and from one other distributor. One login, one card per distributor. The shop sees its own bills, deliveries and dues; it never sees its tier or credit limit, and never another shop's data.

online-first

WhatsApp deep links

pays in bulk every 2–3 orders

Offline sync: why a lost signal never loses an order

Staff phones write locally first. The server never answers an upload with a client error, because that would wedge the phone's queue; a business rejection comes back as a “needs attention” item instead.

staff devices only

never 4xx

replay-safe 180 days

The three state machines the apps share

Every screen reads the same vocabulary. Code never sets a state by hand; it asks the machine for the next state given an event.

VOCABULARY	MEANING ON THE SHOP FLOOR
submitted vs confirmed	Submitted is what the rep did; confirmed is what the business accepted (credit, bargain, floor price cleared). Stock is reserved only on confirmed.
packed	Cartons exist and the invoice number is burnt. From here, changes are credit notes.
settled_with_variance	Cash or pieces did not tie out at check-in; the owner must approve before the trip closes.
written_off	Bad debt decided by the owner; the AR ledger reverses, the invoice stays.

Source: docs/02, 05, 06, 07 and the state machines in shared/domain. Figures show the pilot configuration for Tarsun Enterprises; roles and flows are identical for every distributor tenant.
